Spring Boot REST Internationalization

Ihor Kosandiak · [Follow](#)

4 min read · Oct 30, 2018

[Listen](#)[Share](#)[More](#)

Have you ever faced with challenging task of providing service to your users in their native language? If so — then you may be interested in finding a good approach of doing this.

This guide will show you how is easy, in just couple straightforward steps to make your Spring Boot application to have internationalization. And to handle locales in one single place.

Spring Boot

Internationalization

Nice to see you here guys! Here we will speak about adding internationalization to your existing Spring Boot project. The question of application internationalization becomes not trivial when you are working on the project that should serve users from different countries with different languages. In this cases you will need to provide your user from China with response message in Chinese, and user from France with message in French, so everyone would feel comfortable with your application. So let's take a look how to implement this in Spring Boot.

Let's create project using [Spring Initializer](#) that makes project creation much easier.

The screenshot shows the Spring Initializer web interface. At the top, it says "SPRING INITIALIZR bootstrap your application now". Below that, there's a search bar with "Generate a [Maven Project] with [Java] and Spring Boot [2.0.6]". The main area is divided into two sections: "Project Metadata" and "Dependencies".

Project Metadata:

- Artifact coordinates:
 - Group: com
 - Artifact: demo
- Name: Spring Boot Internationalization
- Description: Demo project for Spring Boot
- Package Name: com.demo
- Packaging: Jar
- Java Version: 8

Dependencies:

- Add Spring Boot Starters and dependencies to your application
- Search for dependencies: Web, Security, JPA, Actuator, Devtools...
- Selected Dependencies: Web

At the bottom right is a green "Generate Project" button.

Then click download project, unzip it and open with your favorite Idea. I'll use IntelliJ IDEA.

First thing what I'll create is our *CustomLocaleResolver* class that will be responsible for defining user's locale.

```
@Configuration
public class CustomLocaleResolver
    extends AcceptHeaderLocaleResolver
    implements WebMvcConfigurer {

    List<Locale> LOCALES = Arrays.asList(
        new Locale("en"),
        new Locale("ru"),
        new Locale("uk"))
}
```

```

        new Locale("fr"));

    @Override
    public Locale resolveLocale(HttpServletRequest request) {
        String headerLang = request.getHeader("Accept-Language");
        return headerLang == null || headerLang.isEmpty()
            ? Locale.getDefault()
            : Locale.lookup(Locale.LanguageRange.parse(headerLang),
LOCALES);
    }

    @Bean
    public ResourceBundleMessageSource messageSource() {
        ResourceBundleMessageSource rs = new
ResourceBundleMessageSource();
        rs.setBasename("messages");
        rs.setDefaultEncoding("UTF-8");
        rs.setUseCodeAsDefaultMessage(true);
        return rs;
    }
}

```

So, here we told that we have 2 locales supported in the project: *en* and *fr*. The locale should be passed in the header called “Accept-Language”. So, if the header is present and it is not empty, we will use locale from it, otherwise — we’ll use default locale, which is *en*.

Next let’s create our class that will be responsible for choosing right message according to specified locale. I’ll call it *Translator*, and it will have one single method, that will accept message code that should be translated.

```

@Component
public class Translator {

    private static ResourceBundleMessageSource messageSource;

    @Autowired
    Translator(ResourceBundleMessageSource messageSource) {
        Translator.messageSource = messageSource;
    }

    public static String toLocale(String msgCode) {
        Locale locale = LocaleContextHolder.getLocale();
        return messageSource.getMessage(msg, null, locale);
    }
}

```

As you can see the `messageSource.getMessage(...)` accepts parameter “`msg`”. But this is not exactly the message that should be translated. It is just message code. For now we don’t have any message codes, so let’s create them.

Read next: What would be possible if all our thoughts were connected and easily accessible?

Meet Journal →

Under the `resources` folder, create two files: `messages.properties` and `messages_fr.properties`.

Here is the content of `messages.properties`:

```
hello=Hello World!
welcome=Welcome to this guide!
```

And here is content of `messages_fr.properties`:

```
hello=Bonjour le Monde!
welcome=Bienvenue dans ce guide!
```

So, here we already can see our message codes. They are “`hello`” and “`welcome`”. And now you can understand what code should we pass to `toLocale(String msgCode)` method in order to get appropriate message according to user’s locale.

And probably the last step is to create simple controller, let’s name it `MainController` that will have just one endpoint, that will accept message code, which we’ll pass into the HTTP request as a request parameter.

```
@RestController
@RequestMapping(value = "/api")
public class MainController {

    @GetMapping()
    public String getMessage(@RequestParam("msg") String msg) {
        return Translator.toLocale(msg);
    }
}
```

So now, let's take a look at our project structure.

The screenshot shows the IntelliJ IDEA interface with the following details:

- Project Structure:** The left sidebar shows the project structure under "spring-boot-internationalization [demo]". It includes:
 - src/main/java:** Contains packages like com.demo.configuration, com.demo.controllers, and com.demo.util. A file MainController.java is open in the editor.
 - src/main/resources:** Contains application.properties, messages.properties, and messages_fr.properties.
 - target:** Contains .gitignore, demo.iml, mvnw, mvnw.cmd, and pom.xml.
- Code Editor:** The main window displays MainController.java with the following code:

```
package com.demo.controllers;
import com.demo.util.Translator;
import org.springframework.web.bind.annotation.GetMapping;
import org.springframework.web.bind.annotation.RequestMapping;
import org.springframework.web.bind.annotation.RequestParam;
import org.springframework.web.bind.annotation.RestController;

@RestController
@RequestMapping(value = "/api")
public class MainController {

    @GetMapping()
    public String getMessage(@RequestParam("msg") String message) {
        return Translator.toLocale(message);
    }
}
```
- Toolbars and Status Bar:** The bottom of the screen shows various toolbars and the status bar indicating the current time (19:11), file encoding (UTF-8), and Git master branch.

And make simple requests using CURL:

The four terminal windows show the following curl commands and their outputs:

- Terminal 1 (Accept-Language: fr):

```
igor@igor-All-Series:~$ curl -X GET -H "Accept-Language: fr" 'http://localhost:8080/api?msg=welcome'
Bienvenue dans ce guide!igor@igor-All-Series:~$
```

- Terminal 2 (Accept-Language: en):

```
igor@igor-All-Series:~$ curl -X GET -H "Accept-Language: en" 'http://localhost:8080/api?msg=welcome'
Welcome to this guide!igor@igor-All-Series:~$
```

- Terminal 3 (Accept-Language: fr):

```
igor@igor-All-Series:~$ curl -X GET -H "Accept-Language: fr" 'http://localhost:8080/api?msg=hello'
Bonjour le Monde!igor@igor-All-Series:~$
```

- Terminal 4 (Accept-Language: en):

```
igor@igor-All-Series:~$ curl -X GET -H "Accept-Language: en" 'http://localhost:8080/api?msg=hello'
Hello World!igor@igor-All-Series:~$
```

So as you see, responses are different based on value of “*Accept-Language*” header passed in the request. This way, we don’t need to check what was passed in the request in each controller method, and then pass it further to service layers. We now can do this in one single place, which is *CustomLocaleResolver* class.

Basically that’s all.

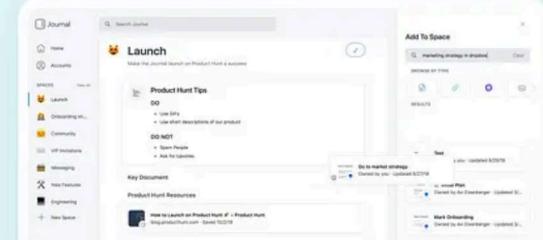

Thank you for your time. Hope you got interesting stuff for you, and enjoyed the reading. As always you can find code sample on my [GitHub](#) account.
